

# Regular Expressions

## Problem

Write a Python code to check if the given mobile number is valid or not. The conditions to be satisfied for a mobile number are:

- a) Number of characters must be 10
- b) All characters must be digits and must not begin with a '0'

# Validity of Mobile Number

Input	Processing	Output
A string representing a mobile number	Take character by character and check if it valid	Print valid or invalid

# Test Case 1

- abc8967891
- Invalid
- Alphabets are not allowed

## Test Case 2

- 440446845
- Invalid
- Only 9 digits

# Test Case 3

- 0440446845
- Invalid
- Should not begin with a zero

# Test Case 4

- 8440446845
- Valid
- All conditions statisfied

## Python code to check validity of mobile number (Long Code)

```
import sys
number = input()
if len(number)!=10:
    print ('invalid')
    sys.exit(0)
if number[0]=='0':
    print ('invalid')
    sys.exit(0)
for chr in number:
    if chr.isalpha():
        print ('invalid')
        break
else:
    print('Valid')
```

- Manipulating text or data is a big thing
- If I were running an e-mail archiving company, and you, as one of my customers, requested all of the e-mail that you sent and received last February, for example, it would be nice if I could set a computer program to collate and forward that information to you, rather than having a human being read through your e-mail and process your request manually.

- Another example request might be to look for a subject line like “ILOVEYOU,” indicating a virus-infected message, and remove those e-mail messages from your personal archive.
- So this demands the question of how we can program machines with the ability to look for patterns in text.
- Regular expressions provide such an infrastructure for advanced text pattern matching, extraction, and/or search-and-replace functionality.
- Python supports regexes through the standard library `re` module

- regexes are strings containing text and special characters that describe a pattern with which to recognize multiple strings.
- Regexs without special characters

Regex Pattern	String(s) Matched
foo	foo
Python	Python
abc123	abc123

---

- These are simple expressions that match a single string
- Power of regular expressions comes in when special characters are used to define character sets, subgroup matching, and pattern repetition

# Special Symbols and Characters

Notation	Description	Example Regex
<b><i>Symbols</i></b>		
<i>literal</i>	Match literal string value <i>literal</i>	foo
<i>re1 re2</i>	Match regular expressions <i>re1</i> or <i>re2</i>	<i>foo bar</i>
.	Match <i>any character</i> (except \n)	b.b
^	Match <i>start of string</i>	^Dear
\$	Match <i>end of string</i>	/bin/*sh\$
*	Match <i>0 or more</i> occurrences of preceding regex	[A-Za-z0-9]*
+	Match <i>1 or more</i> occurrences of preceding regex	[a-z]+\..com
?	Match <i>0 or 1</i> occurrence(s) of preceding regex	goo?
{ <i>N</i> }	Match <i>N</i> occurrences of preceding regex	[0-9]{3}
{ <i>M,N</i> }	Match from <i>M</i> to <i>N</i> occurrences of preceding regex	[0-9]{5,9}
[...]	Match any single character from <i>character class</i>	[aeiou]
[... <i>x-y</i> ...]	Match any single character in the <i>range from x to y</i>	[0-9], [A-Za-z]

# Special Symbols and Characters

## ***Symbols***

---

[^...]

*Do not match* any character from character class, including any ranges, if present

[^aeiou],  
[^A-Za-z0-9\_]

## Matching Any Single Character (.)

- dot or period (.) symbol (letter, number, whitespace (not including “\n”), printable, non-printable, or a symbol) matches any single character except for \n.
- To specify a dot character explicitly, you must escape its functionality with a backslash, as in “\.”

Regex Pattern	Strings Matched
f.o	Any character between “f” and “o”; for example, fao, f9o, f#o, etc.
..	Any pair of characters
.end	Any character before the string end

---

```
import re
if re.match("f.o","fooo"):
    print("Matched")
else:
    print("Not matched")
```

**Output:**

Prints matched

Since it searches only for the pattern 'f.o' in the string

```
import re
if re.match("f.o$", "fooo"):
    print("Matched")
else:
    print("Not matched")
```

Check that the entire string starts with 'f', ends with 'o' and contain one letter in between

```
import re  
if re.match("..", "fooo"):  
    print("Matched")  
else:  
    print("Not matched")
```

Matched

Two dots matches any pair of characters.

```
import re
if re.match("..$", "fooo"):
    print("Matched")
else:
    print("Not matched")
```

Not matched

Including a '\$' at the end will match only strings of length 2

```
import re
if re.match(".end","bend"):
    print("Matched")
else:
    print("Not matched")
```

Matched

The expression used in the example, matches any character for ‘.’

```
import re
if re.match(".end","bends"):
    print("Matched")
else:
    print("Not matched")
```

**Prints Matched**

```
import re
if re.match(".end$","bends"):
    print("Matched")
else:
    print("Not matched")
```

**Prints Not matched - \$ check for end of string**

# Matching from the Beginning or End of Strings or Word Boundaries (^, \$)

^ - Match beginning of string

\$ - Match End of string

Regex Pattern	Strings Matched
<code>^From</code>	Any string that starts with From
<code>/bin/tcsh\$</code>	Any string that ends with /bin/tcsh
<code>^Subject: hi\$</code>	Any string consisting solely of the string Subject: hi

if you wanted to match any string that ended with a dollar sign, one possible regex solution would be the pattern `.*\$$`

## But not sufficient

Check whether the given register number of a VIT student is valid or not.

Example register number – 15bec1032

Register number is valid if it has two digits

Followed by three letters

Followed by four digits

## Denoting Ranges (-) and Negation (^)

- brackets also support ranges of characters
- A hyphen between a pair of symbols enclosed in brackets is used to indicate a range of characters;
- For example A–Z, a–z, or 0–9 for uppercase letters, lowercase letters, and numeric digits, respectively

Regex Pattern	Strings Matched
<code>z.[0-9]</code>	"z" followed by any character then followed by a single digit
<code>[r-u][env-y]</code> <code>[us]</code>	"r," "s," "t," or "u" followed by "e," "n," "v," "w," "x," or "y" followed by "u" or "s"
<code>[^aeiou]</code>	A non-vowel character (Exercise: why do we say "non-vowels" rather than "consonants"?)
<code>[^\t\n]</code>	Not a TAB or \n
<code>["-a]</code>	In an ASCII system, all characters that fall between "" and "a," that is, between ordinals 34 and 97

---

# Multiple Occurrence/Repetition Using Closure Operators (\*, +, ?, {})

- special symbols \*, +, and ?, all of which can be used to match single, multiple, or no occurrences of string patterns
- **Asterisk or star operator (\*)** - match zero or more occurrences of the regex immediately to its left
- **Plus operator (+)** - Match one or more occurrences of a regex
- **Question mark operator (?)** - match exactly 0 or 1 occurrences of a regex.

- There are also brace operators ({}) with either a single value or a comma-separated pair of values. These indicate a match of exactly N occurrences (for {N}) or a range of occurrences; for example, {M, N} will match from M to N occurrences

## Code to check the validity of register number

```
import re
```

```
register= input()
```

```
if re.match("[1-9][0-9][a-zA-Z][a-zA-Z][a-zA-Z][0-9][0-9][0-9][0-9]",register):
```

```
    print("Matched")
```

```
else:
```

```
    print("Not matched")
```

^ - denote begin (Meaning is different when we put this symbol inside the square bracket)

\$ - denote end

Regex Pattern	Strings Matched
[dn]ot?	"d" or "n," followed by an "o" and, at most, one "t" after that; thus, do, no, dot, not.
0?[1-9]	Any numeric digit, possibly prepended with a "0." For example, the set of numeric representations of the months January to September, whether single or double-digits.
[0-9]{15,16}	Fifteen or sixteen digits (for example, credit card numbers).

## Refined Code to check the validity of register number

{n} – indicate that the pattern before the braces should occur n times

```
import re
```

```
register= input()
```

```
if re.match("^[1-9][0-9][a-zA-Z]{3}[0-9]{4}$",register):
```

```
    print("Matched")
```

```
else:
```

```
    print("Not matched")
```

## Check validity of Mobile Number (Shorter Code)

```
import re
number = input()
if re.match('[^0][0-9]{9}', number):
    print('valid')
else:
    print('invalid')
```

Bug: Will also accept a843338320

## Check validity of Mobile Number (Shorter Code)

```
import re
```

```
number = input()
```

```
if re.match('[1-9][0-9]{9}',number):
```

```
    print('valid')
```

```
else:
```

```
    print('invalid')
```

## Check validity of PAN card number with RE

```
import re
pan=input()
if len(pan) < 10 and len(pan) > 10 :
    print ("PAN Number should be 10 characters")
    exit
elif re.search("[^a-zA-Z0-9]",pan):
    print ("No symbols allowed, only alphanumerics")
    exit
elif re.search("[0-9]",pan[0:5]):
    print ("Invalid - 1")
    exit
elif re.search("[A-Za-z]",pan[5:9]):
    print ("Invalid - 2")
    exit
elif re.search("[0-9]",pan[-1]):
    print ("Invalid - 3")
    exit
else:
    print ("Your card "+ pan + " is valid")
```

Python read all input as string

In some cases it is necessary to check if the value entered is an integer

We can check it using regular expressions

### Rules for an integer

optionally begin with a negative sign include ^ symbol

first digit must be a number other than zero

may be followed zero to any number of digits

string must end with it so add \$ symbol

```
import re
```

```
register= input()
```

```
#optionally begin with a negative sign include ^ symol
```

```
#first digit must be a number other than zero
```

```
# may be followed zero to any number of digits
```

```
# string must end with it so add $ symbol
```

```
if re.match("^\\-?[1-9][0-9]*$",register):
```

```
    #'\\' is added in front of '-' to overcome its default  
    meaning in REs
```

```
    print("Matched")
```

```
else:
```

```
    print("Not matched")
```

## Rules for an integer or a floating point value

optionally begin with a negative sign include ^ symbol

first digit must be a number other than zero

may be followed zero to any number of digits

string must end with it so add \$ symbol

Optionally followed by a ‘.’

Followed by zero or more digits

String ends here

```
import re
register= input()
if re.match("^\\-?[1-9][0-9]*\\.?[0-9]*$",register):
    # '.' can occur zero or one time followed by a
    # digit occurred zero to infinite number of times
    print("Matched")
else:
    print("Not matched")
```
